Mashiny i apparaty ustanovok razdeleniya vozdukh na metodom glubokogo okhlazhdeniya; atlas konstruktsey (Machinery and Apparatus for Air Separation by Low-Temperature Refrigeration; Atlas of Designs) Moscow, Mashgiz, 1959. 189 p. Errata slip inserted. 5,000 copies printed.

Ed.: I.F. Usyukin, Doctor of Technical Sciences, Professor; Reviewers: I.K. Kondryakov, Candidate of Technical Sciences, and M.P. Malkov, Doctor of Technical Sciences, Professor; Eds.: P.M. Ionov, Engineer, B.N. Bol'shakov, and N.S. Kasperovich; Managing Ed. for Catalogs and Albums: K.A. Ponomareva, Engineer; Tech. Ed.: A.Ya. Tikhonov.

PURPOSE: This atlas is intended as a design manual for students of schools of higher technical education and can be used by planning and design offices and scientific research institutes in the study of problems of low-temperature refrigeration and the use of oxygen as a means of raising industrial output.

Card-1/12.

Machinery and Apparatus (Cont.)

807/3922

COVERAGE: The atlas contains basic designs of Soviet and non-Soviet plants for separating air by the low-temperature refrigeration method. Also included are types of expansion engines and turbines, pumps for liquid oxygen, basic types of heat exchangers and rectification equipment used in oxygen and nitrogen plants, containers for storage and transportation of liquid gases, and auxiliary apparatus for drying and cleaning air. The operation of typical accessories under low-temperature conditions is shown. No personalities are mentioned. There are no references.

TITLE: Heat treatment of low-carbon and low-alloy steel plate

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 11, 1965, 20-21

TOPIC TAGS: metal heat treatment, tempering, cooling, ferritic steel, pearlite steel

ABSTRACT: The Ukrainian Scientific Research Institute of Metals in collaboration with the TENIICHERMET and the Kommunar Metallurgical Plant developed a new industrial process of the heat treatment (quenching and tempering) of St. 3 steel plates: quenching from 890-910°C and water cooling in the press, followed by tempering at 500°C. At the Kommunar Plant the thermal hardening is carried out in continuous roller hearth furnaces. Plate 4-50 mm thick and up to 12 m long can be cooled in the press. The squeeze exerted by the press is 130 tons; the water-spray pressure is 2-3 atm. The microstructure of the plate is initially (after rolling) ferritic with a small amount of pearlite; following thermal hardening this microstructure is pearlitic-ferritic (the amount of pearlite increases). Studies of the mechanical properties of St. 3ps steel before and after this heat treatment revealed a marked increase in the impact strength of thermally hardened steel (3.9-7.4 kg-m/cm²) compared with the im-

ACC NR: AP5027704

fact strength of the nonhardened steel ($1-1.7 \text{ kg-m/cm}^2$) at temperatures as low as -40°C . In both cases the threshold of cold brittleness is the same, -25 to -30°C . Thermal hardening enhances the fatigue limit from 6 to 32% and reduces susceptibility to stress concentration. This technique of heat treatment was experimentally tested not only in furnaces but also in rolling mills on employing a special installation for utilizing the heat of rolling in order to increase the mechanical properties of the plate. In addition, the effect of accelerated water cooling was also investigated for the steels 14KhGS, SKhL-4, 09G2, 1S, SK, M16S, 3M, 20K (plate thickness 10-24 mm). Findings: thermal hardening during rolling increases tensile and yield strength by an average of 2-4 kg per mm^2 and impact strength, by 0.5-1.5 kg-m/cm^2 , while at the same time reducing relative elongation by ~2%, i. e. the increase in mechanical properties is considerable. As the thickness of the steel plate increases, the effect produced by water cooling decreases, and in the presence of 20-mm thickness this effect no longer is active. Orig. art. has: 1 figure.

rate of 1700 m³/hr. After quenching, some warpage could be noted, particularly in
specimens 4 to 20 mm. Mechanical properties of the heat treated plate in flat and
bump specimens were determined. Yield strength, ultimate strength, elongation, and
hardness were determined. The results were related for heat I (12 mm thick), heat
II (12 mm thick), and heat III (12 mm thick). The results are given in the
appendix. The average values are given in the table below.

There was some warpage noted in the specimens. The mechanical properties of the
specimens were related to the heat treated condition. The yield strength
was related to the heat treated condition. The ultimate strength was related to the
heat treated condition. The elongation was related to the heat treated condition.
The hardness was related to the heat treated condition. It was recommended that low carbon steel plate, strength
the above treatment, be used in place of low alloyed steel. To be effective the opti-
mum carbon content for heat treatment should be 0.12-0.18%. Orig. ut has 3 figures,
2 tables.

Refractories

Indices of chemical activation of refractories on the combustion of hydrogen. M. B. HAYDON AND R. A. KAMMAYOR. (Soviet Acad. Sci. U. S. S. R., 1948-49 (1949) (in English); Chem. Abs., 44, 6424 (1949)).—Reaction rates were studied with stoichiometric mixtures of H and O₂ in packed and unpacked quartz tubes at 600, 700, 850, 900, and 950° and an initial pressure of approximately 1 atm. Hg. The rate of reaction is increased at low temperatures by the presence of commercial grog with surface coatings of Ni and Fe oxides and by Ural dunite. The activated grog and dunite yielded rates at 400° comparable to the rate obtained with the unactivated refractory at 950°. High-temperature annealing had little effect on the activities of these two refractories.

F 1320. CATALYTIC COMBUSTION OF EXHAUST GASES OF INTERNAL COMBUSTION ENGINES. Zaharov, B. A. and Nicolae, T. M. (Izvestia Akad. Nauk, US.S.R., Otdel. Tech. Nauk, 1948, (1), 79-86; abstr. in Engng. Abstr., Sect. 3, Sept. 1948, vol. 11, 86).

The combustion of gas-air mixtures in which the gas concentration is below the ignition limit or the temperature of which is below the ignition temperature cannot take place in the form of a flame. There are many cases in which the gases contain noxious and toxic constituents (mainly carbon monoxide). It has been proposed by M. B. Ravitch that the problem be solved by the employment of a catalyst which permits the complete combustion at high speed at temperatures of 500 to 600 deg. C. The practical solution of this problem, however, requires the discovery of catalysts which are highly effective, do not deteriorate and are low in cost and easy to manufacture. Investigations of the combustion of hydrogen and also of carbon monoxide and mixtures of hydrogen and methane passed through both ordinary and activated refractories have been carried out at the Institute of Energetics of the Soviet Academy of Science under varying conditions of temperature

and pressure; they have shown that activated refractories are well suited to serve as catalysts for the combustion of gases. Particular interest is attached to experiments conducted with fire clay activated by a mixture of oxides of iron and manganese as suggested by B. A. Zaharov. These experiments were conducted with the exhaust gases of a petrol engine. In the tests referred to in the present article a mixture of exhaust gas with air was passed through a refractory layer at atmospheric pressure and at temperatures of 300 to 500 deg. C. respectively. The velocity of flow ranged from 0.15 to 6 metres per second and the contact speed varied from 1,000 to 20,000 litres of gas mixture per litre of refractory per hour. The efficacy of the refractory as a catalyst was assessed on the basis of the degree of completeness of combustion of the exhaust gas. Detailed data on the experimental apparatus used is also included in the article. The following conclusions were arrived at by the investigators. By activating an ordinary fire clay refractory with oxides of various metals (palladium or mixtures of copper-manganese, iron-manganese) the combustion of exhaust gases from internal combustion engines is assisted. In the case of laminar flow of the exhaust gas through the refractory with a short length of contact complete combustion of the exhaust gas is obtained at moderate temperatures. In the case of unstable, turbulent flow the efficacy of the various catalysts diminishes in the following order: copper-manganese, palladium, iron-manganese, the last showing the greatest decline. An increase in the length of travel through the refractory layer will compensate for the drop in the degree of

(2)

completeness of combustion with the gas velocity, and such an increase in the length of contact will also tend to diminish the differences in the relative efficacies of the various catalysts. Fire clay activated by a mixture of oxides of iron and manganese represents a catalyst which is low in cost and easily obtainable. It is capable of producing complete combustion of the exhaust gases at high flow velocity at the temperature with which the gases are exhausted from the internal combustion engine.

Calculation of the molecular weights of cellulosic materials from the constants of sedimentation or diffusion. B. A. Zakharenko, *Izv. Akad. Nauk S.S.S.R. Khim. N. 1, 1951*. Mol. wt. M are calculated by the formula $M = \frac{RTS}{D(1 + K)c} - \frac{1}{\rho}$ (where c = concn., S = partial sp. vol. of the dissolved substance, ρ = d., and S and D , resp., the rate consts. of sedimentation and of diffusion extrapolated to $c = 0$), from data of S_0 and D_0 of N. Gralen (Thesis, Uppsala, 1944) for a no. of native and treated celluloses, including bleached, acetylated, sulfite, alkali-treated, etc., in Cu ammoniacal soln. The data agree fairly well with the empirical formulas $M = 0.29 \times 10^6 D_0^{0.6}$ and $M = 0.44 \times 10^6 S_0^{0.6}$, which can be combined into $S_0 = 0.321 \times 10^{-6} D_0^{0.6}$. N. TITLE:

Molecular Homogeneity and Properties of Cellulose
(Molekul'naya gomogenost' i svoystva tsellyulozy)

PERIODICAL:

Doklady Akademii Nauk SSSR, 1958, Vol 122, Nr 5,
pp 814 - 816 (USSR)

ABSTRACT:

For some time the opinion was prevalent that the molecular weight of cellulose as a highly molecular compound (Refs 1-4) amounted to about 500 000 (Ref 5). However, viscosimetric measurements and the retardation of oxydative degradation yielded a figure of about 1, 600 000 for this weight (Refs 6-8). Recently this was confirmed (Refs 9-11). As early as 1939, strange and hardly explicable observations were made (Refs 12-13): the properties of strength of the natural cellulose fibres became obvious in a solid state at an average molecular weight (\bar{M}) of about 32 000 and increase rapidly with an increase of \bar{M} up to 113 000; then the increase of strength is

Card 1/4

Molecular Homogeneity and Properties of Cellulose

SCV/20-122-5-18/56

constantly reduced up to 100 000 above which it
 no longer constant. Furthermore it was discovered
 that cellulose is heterogeneous with respect to the
 length of chain molecules (Refs 14, 15). Therefore
 that above figure of molecular weight must be
 considered as an average value depending undoubtedly
 on the method of measuring. A general idea of the
 heterogeneity of cellulose is offered by the average
 coefficient of heterogeneity.

$$\bar{U} = \frac{\bar{M}_{\text{weight}}}{\bar{M}_{\text{num}}} - 1, \text{ in which } \bar{M}_{\text{weight}} \text{ and } \bar{M}_{\text{num}} \text{ are the}$$

molecular weights: average by weight and numerical
 average, respectively. In modern studies the hetero-
 geneity of cellulose is described more completely
 and more accurately by means of functions of integral
 and differential calculus (Ref 16). At present
 some tests are conducted in order to estimate the
 changes in heterogeneity in different processes of
 isolation and production and to combine the heterogeneity

Card 2/4

Molecular Homogeneity and Properties of Cellulose

SOV/20-122-5-18/56

with the quality of the cellulose products. This, however, was rather complicated and afforded little hope of success. The authors wanted to tackle the task of specifying the problem of chain molecule length. The more precise concept and meaning of homogeneity of cellulose served them well in this work. According to their opinion, two characteristics of homogeneity, which can be determined on the curve of mass distribution, are of decisive importance; a) the degree of homogeneity (mono-dispersion), which expresses the physical nature of the phenomenon. This characteristic is defined by the height and basis of the maximum on the curve. b) the other characteristic is determined by the degree of polymerization(P), which corresponds to the maximum. As a consequence, the super-molecular structure of cellulose (opposite position of molecules and inter-molecular bonds) can and must be determined by the degree of molecular homogeneity. The authors proved this in experiments. Nitric ethers produced from cellulose in finished

products were fractionated according to the method of precipitation (Ref 10). Examples are given and explained by means of curves (Fig 1, curves 1-4). There are 1 figure and 10 references, 4 of which are Soviet.

TITLE:

A Chemical Method of Homogenizing Cellulose With Respect to
Molecular Weight (Khimicheskiy metod gomogenizatsii tsell-
yulozy po molekulyarnomu vesu)

PERIODICAL:

Doklady Akademii nauk SSSR, 1958, Vol 123, Nr 4,
pp 691 - 692 (USSR)

ABSTRACT:

In an earlier report by the authors (Ref 1) their theoretical
ideas that the strength of the cellulose products is closely
connected with the homogeneity of the cellulose with respect
to the length of the chain molecules, was proved. From the
data in publications it may be concluded that during the in-
dividual production stages (Refs 3-6) no considerable homo-
geneity of cellulose is obtained. The authors have investigated
the absorption of acids by cellulose from aqueous solution.
Cotton cellulose was used for these experiments as well as
chemical (sulfate) wood pulp. It was treated with HNO_3

Card 1/3

(concentration 0.2 n at 92°) (cotton cellulose for 1 hour,

A Chemical Method of Homogenizing Cellulose With Respect to Molecular Weight SOV/20-123-4-32/53

chemical wood pulp for half an hour). Furthermore the cotton cellulose was treated under the same conditions with HCl. Figures 1 and 2 show the results obtained: the cotton cellulose (Fig 1, Curves 1 and 2) is to a large extent heterogeneous with respect to its molecular weight. The treatment of cotton cellulose led to a degradation of long chain molecules with a definite homogenization (Curve 4), whereas the effect of nitric acid was accompanied by a considerable homogenization (Curve 3). The treatment of the sulfate chemical wood pulp according to the method of the institute (IOKh AS USSR) mentioned under Association leads to a physical-chemical homogenization of the cellulose. The maximum on the mass distribution curve is at $P = 850$ (Fig 2, Curve 2). HNO_3 causes the displacement of this maximum into the low-molecular range, i.e. $P = 220$. The results obtained make it possible to draw the conclusion that HNO_3 may be used for the homogenization mentioned in the title. The high degree of homogenization can be reached at a desired degree of polymerization by the selection of the conditions of the combined physico-chemical homogenization (concentration, temperature, duration). Thus,

Card 2/3

A Chemical Method of Homogenizing Cellulose With Respect to Molecular Weight SOV/20-127-4-32/53

an appropriate strength of various cellulose products can be obtained. There are 2 figures and 11 references, 3 of which are Soviet.

Letters to the Editor (Pis'ma redaktoru)

PERIODICAL:

Izvestiya Akademii nauk SSSR. Otdeleniye khimicheskikh nauk,
1959, Nr 5, p 949 (USSR)

ABSTRACT:

In earlier papers (Refs 1-3) the authors had shown that the strength of a hydrated cellulose fiber may be determined mainly from the homogeneity of the molecular weight of the cellulose. Accordingly, the molecular homogeneity of bleached sulfite paper with known strength characteristics was investigated after a single deformation (double folding). Papers of the type A, and papers made by the firms Aane and Serlakis were investigated. The mass distribution function in dependence on the degree of polymerization is represented by a figure for the various types of paper. Investigations showed that, in order to attain a high degree of strength, a very homogeneous cellulose in the range of polymerization above 2000 is necessary. This may be attained by using a cellulose for paper production,

TITLE:

The Homogenization of Cellulose With Respect to Molecular Weight in the Process of Bleaching by Activated Oxidation

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 2, pp 396 - 397 (USSR)

ABSTRACT:

The results obtained by the authors and the data given in the publications show that the usual chemical methods of cellulose working to hydrate cellulose fibers are not able to guarantee the production of highly solid structural-homogeneous fibers. Although the processes used change, as a rule, the heterogeneity of the molecular weight, they do not cause a considerable homogeneity of cellulose. Therefore it became a topical object to estimate the mentioned processes from the point of view of the change in homogeneity and to change these processes in the necessary direction. The treatment of cotton- as well as of wood cellulose with diluted nitric acid causes a far-reaching homogeneity (Ref 3). In contrast to this, a modification

Card 1/3

The Homogenization of Cellulose With Respect to
Molecular Weight in the Process of Bleaching by Activated Oxidation

SOV/20-127-2-45/70

of the usual factors alone is not successful (Ref 4). From figure 1 follows that the usual bleaching of the sulphite cellulose of wood only reduces the homogeneity (Ref 5). In this connection it was interesting to modify the oxidation process upon which the bleaching with sodium hypochlorite is based. Therefore the authors investigated the topic mentioned in the title. Urea served as activator. The cellulose preparations of G. A. Krylova (Ref 6) were investigated. The figure 2:3 shows the distribution of the molecular weight of the sulphate cellulose which served, partly bleached and refined with alkali, as initial cellulose. The figure 2:1 shows that no homogenization proceeds if sodium hypochlorite influences this cellulose. A considerable specific homogenization is, in contrast to this, obtained, if the activated oxidation is used (preliminary treatment of the cellulose with urea) and the cellulose treated with hypochlorite oxidized after that. The above homogenization is bound to be connected with the increased accessibility of the long chain molecules for the oxidizing agent if the duration of the activated oxidation amounts to only 1/10 of the usual one, and the content of carbonyl- and carboxyl groups in the bleached

Card 2/3

The Homogenization of Cellulose With Respect to SOV/20-127-2-45/70
Molecular Weight in the Process of Bleaching by Activated Oxidation

celluloses is on the whole equal (Ref 6). The specific degradation proceeding here increases the quantity of the molecules with the polymerization degree 800. It may therefore be expected that the use of catalysts or activators will establish conditions which guarantee a specific degradation and increase of the homogeneity of cellulose with respect to its molecular weight in several chemical working processes of cellulose materials and in their working to hydrate cellulose fibers. There are 2 figures and 6 references, 5 of which are Soviet.

TITLE: Influence of the degree of perfection of Ge and GaAs on the jump of the integral intensity at the K absorption edge 27 27 27

SOURCE: Kristallografiya, v. 11, no. 2, 1966, 227-235

TOPIC TAGS: germanium, gallium arsenide, crystal imperfection, epitaxial growing, single crystal, absorption edge, x radiation, radiation intensity, crystal dislocation phenomenon

ABSTRACT: The author investigated the perfection of Ge and GaAs by recording the intensity discontinuity in the region of the K absorption edge, with an aim of ascertaining the applicability of this method to investigations of the perfection of single crystals. The results of the investigation are compared with the data obtained by the x-ray diffraction method. The observed jump in intensity is in good agreement with the theoretical values calculated on the basis of the dynamical theory developed by W. H. Zachariasen (Theory of X-ray Diffraction in Crystals, John Wiley, New York, 1945). The jump in intensity was independent of the dislocation

limation method. The observed jump in intensity is in good agreement with the theoretical values calculated on the basis of the dynamical theory developed by W. H. Zachariasen (Theory of X-ray Diffraction in Crystals, John Wiley, New York, 1945). The jump in intensity was independent of the dislocation

Production of castings from quality cast iron. The
 Summary report. M. B. Khannalov and H. P. Likhachev.
 N. S. Khannalov. Vsesoyuznyy Inst. Metal. Y. 75-11(111).
 Methods are described for the prep. of cast iron with
 better phys. and mech. properties than the usual gray
 cast iron. The C content of an iron melted in a rapid
 furnace rarely falls below 2.0%, and when it does, it is
 more or less accidental. A cast iron with a min. C con-
 tent possesses some undesirable properties, among others,
 a considerable decrease in the temp. of casting. The
 authors suggest increasing the temp. of casting. At a
 temp. of 1250°, samples were obtained which showed a
 tensile strength of 65 kg per sq mm, whereas samples
 cast at 1200° showed a tensile strength of only 40-45
 kg. per sq. mm H. C. Chen

Determination of the yield point of high-chromium stainless steels by indentation with a cone. M. P. Sitchikov, B. P. Zakharov, and Yu. V. Kozlov. *Zaodnyye Lab.*, 13, 654-8(1967).—The yield point of 2 types of high-Cr stainless steel was determined in the annealed and the quenched and tempered (500-800°) states by measuring the deformation produced by a Rockwell machine with (a) a 100-kg. load on a steel cone with a 90° angle, and (b) a 150-kg. load on a diamond cone with a 130° angle. The yield point was calculated from the equation $\sigma_0 = P/\pi r_0^2$, where P was the load applied and r_0 was the max. radius of the elevated zone around the impression. The actual yield point of the samples tested, as determined by the usual destructive test, ranged from 25.5 to 135.5 kg./sq. mm. The results from the steel cone differed from the rupture test by -9.8 to +7.6%, while the diamond cone values differed by -10.1 to +12.0%. H. W. Rathmann

*178. Determination of the Mechanical Properties of Steel Without Use of Tensile Specimens. (In Russian.) M. F. Shtikov, B. P. Zakharov, and Yu. V. Kozlova. *Zavodskaya Laboratoriya* (Factory Laboratory). v. 13, Dec. 1947, p. 1463-1471; discussion, p. 1471.

The possibility of indirect determination of the 4 basic factors involved in mechanical strength (tensile strength, yield point, per cent elongation, and per cent reduction of area) by use of a cone indenter was investigated theoretically and experimentally. Results so far are favorable, but further work is needed for complete verification. The editor comments adversely.
